Lab: Objects and Classes

Problems with exercise and homework for the "JS Front-End" Course @ SoftUni.

1. Person Info

Write a function that receives **3 parameters**, sets them to an **object**, and **returns** that object.

The input comes as **3 separate strings** in the following order: **firstName**, **lastName**, **age**.

Examples

Input	Object Properties
"Peter", "Pan", "20"	<pre>firstName: Peter lastName: Pan age: 20</pre>
"George", "Smith", "18"	<pre>firstName: George lastName: Smith age: 18</pre>

Hints

```
function personInfo(firstName, lastName, age) {
    //TODO: Create the person object and set the properties
  return person;
}
```

2. City

Write a function that receives a **single parameter** – an **object**, containing **five properties**:

```
{ name, area, population, country, postcode }
```

Loop through all the keys and print them with their values in format: "{key} -> {value}" See the examples below.

Examples

	Input	Output
{		name -> Sofia
	name: "Sofia",	area -> 492
	area: 492,	population -> 1238438
	population: 1238438,	country -> Bulgaria

```
country: "Bulgaria",
                                                 postCode -> 1000
    postCode: "1000"
}
{
    name: "Plovdiv",
                                                 name -> Plovdiv
                                                 area -> 389
    area: 389,
    population: 1162358,
                                                 population -> 1162358
    country: "Bulgaria",
                                                 country -> Bulgaria
    postCode: "4000"
                                                 postCode -> 4000
}
```

3. City Taxes

This task is an extension of Problem 1, you may use your solution from that task as a base.

You will receive a city's name (string), population (number), and treasury (number) as arguments, which you will need to set as properties of an object and return it. In addition to the input parameters, the object must have a property taxRate with an initial value of 10, and three methods for managing the city:

- collectTaxes() Increase treasury by population * taxRate
- applyGrowth(percentage) Increase population by given percentage
- applyRecession(percentage) Decrease treasury by given percentage

Round down the values after each calculation.

Input

Your solution will receive three valid parameters. The methods that expect parameters will be tested with valid input.

Output

Return an object as described above. The methods of the object modify the object and don't return anything.

Input	Output
<pre>const city = cityTaxes('Tortuga', 7000, 15000); console.log(city);</pre>	<pre>{ name: 'Tortuga', population: 7000, treasury: 15000, taxRate: 10, collectTaxes: [Function: collectTaxes], applyGrowth: [Function: applyGrowth], applyRecession: [Function: applyRecession] }</pre>
Testing with code	
Input	Output

```
const city =
                                          85000
  cityTaxes('Tortuga',
                                          7350
  7000,
  15000);
city.collectTaxes();
console.log(city.treasury);
city.applyGrowth(5);
console.log(city.population);
```

4. Convert to Object

Write a function that receives a string in JSON format and converts it to an object.

Loop through all the keys and print them with their values in format: "{key}: {value}"

Examples

Input	Output
'{"name": "George", "age": 40, "town": "Sofia"}'	name: George age: 40 town: Sofia
'{"name": "Peter", "age": 35, "town": "Plovdiv"}'	name: Peter age: 35 town: Plovdiv

Hints

Use JSON.parse() method to parse JSON string to an object

```
function solve(jsonStr) {
    let person = JSON.parse(jsonStr);
    //TODO: Iterate through the properties and
    //TODO: print the result
solve('{"name": "George", "age": 40, "town": "Sofia"}');
```

5. Convert to JSON

Write a function that receives a first name, last name, hair color and sets them to an object.

Convert the **object** to **JSON string** and print it.

Input is provided as **3 single strings** in the order stated above.

Examples

Input	Output
'George', 'Jones', 'Brown'	{"name":"George","lastName":"Jones","hairColor":"Brown"}
'Peter', 'Smith', 'Blond'	{"name":"Peter","lastName":"Smith","hairColor":"Blond"}

Hints

Use JSON.stringify() to parse the object to JSON string

```
function solve(name, lastName, hairColor) {
    //TODO: Create an object with the given input
    console.log(JSON.stringify(person));
solve('George', 'Jones', 'Brown');
```

6. Phone Book

Write a function that stores information about a person's name and phone number. The input is an array of strings with space-separated name and number. Replace duplicate names. Print the result as shown.

Example

Input	Output
['Tim 0834212554',	Tim -> 0876566344
'Peter 0877547887',	Peter -> 0877547887
'Bill 0896543112',	Bill -> 0896543112
'Tim 0876566344']	
['George 0552554',	George -> 0453112
'Peter 087587',	Peter -> 087587
'George 0453112',	Bill -> 0845344
'Bill 0845344']	

7. Meetings

Write a function that manages meeting appointments. The input comes as an array of strings. Each string contains a weekday and person's name. For each successful meeting, print a message. If you receive the same weekday twice, the meeting cannot be scheduled so print a conflicting message. In the end, print a list of all successful meetings.

Example

Input	Output
['Monday Peter',	Scheduled for Monday
'Wednesday Bill',	Scheduled for Wednesday

'Monday Tim',	Conflict on Monday!
'Friday Tim']	Scheduled for Friday
	Monday -> Peter
	Wednesday -> Bill
	Friday -> Tim
['Friday Bob',	Scheduled for Friday
'Saturday Ted',	Scheduled for Saturday
'Monday Bill',	Scheduled for Monday
'Monday John',	Conflict on Monday!
'Wednesday George']	Scheduled for Wednesday
	Friday -> Bob
	Saturday -> Ted
	Monday -> Bill
	Wednesday -> George

8. Address Book

Write a function that stores information about a person's name and his address. The input comes as an array of strings. Each string contains the name and the address separated by a colon. If you receive the same name twice just **replace** the address. In the end, print the full list, **sorted alphabetically** by the person's name.

Input	Output
['Tim:Doe Crossing',	Bill -> Ornery Rd
'Bill:Nelson Place',	Peter -> Carlyle Ave
'Peter:Carlyle Ave',	Tim -> Doe Crossing
'Bill:Ornery Rd']	
['Bob:Huxley Rd',	Bill -> Gateway Way
'John:Milwaukee	Bob -> Redwing Ave
Crossing',	George -> Mesta
'Peter:Fordem Ave',	Crossing
'Bob:Redwing Ave',	Jeff -> Huxley Rd
'George:Mesta	John -> Grover Rd
Crossing',	Peter -> Huxley Rd
'Ted:Gateway Way',	Ted -> Gateway Way
'Bill:Gateway Way',	
'John:Grover Rd',	
'Peter:Huxley Rd',	
'Jeff:Gateway Way',	
'Jeff:Huxley Rd']	

9. Cats

Write a function that receives array of strings in the following format '{cat name} {age}'.

Create a Cat class that receives in the constructor the name and the age parsed from the input.

It should also have a method named "meow" that will print "{cat name}, age {age} says Meow" on the console.

For each of the strings provided, you must create a cat object and invoke the .meow () method.

Examples

Input	Output
['Mellow 2', 'Tom 5']	Mellow, age 2 says Meow Tom, age 5 says Meow
['Candy 1', 'Poppy 3', 'Nyx 2']	Candy, age 1 says Meow Poppy, age 3 says Meow Nyx, age 2 says Meow

Hints

- Create a Cat class with properties and methods described above
- Parse the input data
- Create all objects using the class constructor and the parsed input data, store them in an array
- Loop through the array using for...of a cycle and invoke .meow() method

```
function solve(arr) {
    let cats = [];
    //TODO: Create class Cat
    for (let i = 0; i < arr.length; i++) {
        let catData = arr[i].split(' ');
        let name, age;
        [name, age] = [catData[0], catData[1]];
        cats.push(new Cat(name, age));
    //TODO: Iterate through cats[] and invoke .meow() using for...of loop
}
solve(['Mellow 2', 'Tom 5']);
```

Songs **10.**

Define a class Song, which holds the following information about songs: typeList, name, and time.

You will receive the input as an **array**.

The first element **n** will be the number of songs. Next **n** elements will be the songs data in the following format: "{typeList}_{name}_{time}", and the last element will be typeList / "all".

Print only the names of the songs, which have the same typeList (obtained as the last parameter). If the value of the last element is "all", print the names of all the songs.

Examples

```
[3,
                                    DownTown
'favourite_DownTown_3:14',
                                    Kiss
                                    Smooth Criminal
'favourite_Kiss_4:16',
'favourite Smooth Criminal 4:01',
'favourite'l
                                    Andalouse
[4,
'favourite DownTown 3:14',
'listenLater_Andalouse_3:24',
'favourite_In To The Night_3:58',
'favourite_Live It Up_3:48',
'listenLater']
[2,
                                    Replay
'like_Replay_3:15',
                                    Photoshop
'ban_Photoshop_3:48',
'all']
```

Solution:

Create a **Song class** with properties described above

```
class Song {
    constructor(type, name, time) {
        this.type = type;
        this.name = name;
        this.time = time;
```

Create a new array, where you will store songs

```
let songs = [];
let numberOfSongs = input.shift();
let typeSong = input.pop();
```

Iterate over the songs:

```
for (let i = 0; i < numberOfSongs; i++) {</pre>
    let [type, name, time] = input[i].split('_');
    let song = new Song(type, name, time);
    songs.push(song);
```

```
if (typeSong === 'all') {
    songs.forEach((i) => console.log(i.name));
   let filtered = songs.filter((i) => i.type === typeSong);
   filtered.forEach((i) => console.log(i.name));
```
